Testing Report

Introduction

Testing is the process of examining software's behaviour to check that it meets the required specifications of services without errors arising. The process provides information concerning the software under the conditions that the test is run under; however, it only guarantees that the software will not fail under those specific conditions. Thus, it is imperative that the companies testing strategy is comprehensive and covers most facets of the service to avoid undetected faults. Achieving large test coverage manually would require people hours from the company, increasing the cost and length of development. To tackle this problem, this report outlines a testing strategy making use of both manual and automated, computer-operated test strategies to achieve high coverage testing without major slowdowns in releases, or considerable expansions to testers and the quality assurance team.

Automated Testing

The company makes extensive use of automated testing throughout development and deployment. Automated testing allows developers to monitor if any defects are present in the codebase without manually testing and searching for errors, saving time. A report by the National Institute of Standards & Technology (2002) reports software bugs are estimated to have cost the United States of America \$59.5 billion annually. They estimated that approximately \$22.5 billion, a third of the cost, could be saved through improvements to testing infrastructure. The impact of automated testing is not only observed on the macro scale, but also on the team scale. Salesforce, a customer relationship management software provider, reported the following reductions after implementing automated testing: the amount of staff involved in application deployment reduced by 65%, two to 3 hours of final testing was reduced to 10 minutes of automated tests, 3 to 4 hours of post-release testing was handled by 45 minutes automated testing, the patch release team was reduced by 80%, and, overall, Salesforce acheived savings of 300 hours per major release (Cohn, 2009). On the other hand, automated testing has the following disadvantages: it has higher initial costs than manual testing, knowledge of the test tools is required, the tests require maintenance, and implementing testing requires either a developer or testing specialist (Umar and Chen, 2019). Despite these disadvantages, when automated testing is implemented early into a project's development its advantages far outweigh its detriments. Catching errors early without manual testing reduces the cost of finding and then solving them. Furthermore, it improves the structure of the project by clearly defining goals and user journeys, as seen in processes like test-driven development. Overall, automated testing is an extremely valuable area with a significant role in the company's development process.

Testing pyramid

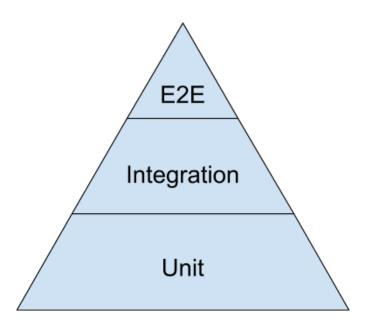

Figure 2: Testing Pyramid (Wacker, 2015)

The companies automated test structure follows the testing pyramid strategy created by Mike Cohn (2009). His initial interpretation was a pyramid with 3 levels. The bottom being unit testing, then service testing, and finally, at the top, user interface testing. Various interpretations have stemmed from Mike Cohn's original design, renaming the pyramid's stages or by adding additional layers. However, it is agreed that the lowest layers receive the highest time and processing investment with the largest number of tests. As you ascend the pyramid's layers, the tests become more infrequent with lower investment. As seen in figure 2, unit tests have the highest amount of tests; whereas, end-to-end (E2E) and user interface tests number far fewer, running less frequently. This is because end-to-end tests, whilst comprehensive, have several disadvantages. Cohn (2009) lists the drawbacks as, fragility, time cost, and processing cost. E2E tests are brittle; small changes in the program's user interface could break several tests. Repeated fixes create discontent and a reluctance to fix the broken test, leaving it useless. Moreover, effective, non-brittle E2E testing increases development time costs, making a large E2E test suite impractical. Finally, E2E testing costs more computationally than unit and integration testing, therefore tests can not run as frequently, decreasing daily coverage compared to unit and integration testing. On the other hand, unit testing, despite being quick, only deals with small independent slices of the program, lacking coverage on external services and how they integrate with each other. Therefore, service, or integration testing, acts middleman to avoid testing external dependencies such as databases, APIs and user input through the user interface.

The explanation on the testing pyramid provided short insights into the stages. The following will

explain each layer in further depth and provide examples implementations from the company.

Unit tests

The first stages of testing occur during the development and programming process. The company uses unit tests as its foundation; these tests involve writing isolated automated tests targeting small sections of the program, known as units. A single project can have many unit tests; a common amount is one unit test per production class, however even more can be added. Creation of the unit test involves developing a criteria, referred to as the test case. The criteria should not be too strict, otherwise the test would break every time code is changed, but it should not be too general either. A good way to implement unit tests is through check observable behaviours; Martin Fowler (2018b), states, 'think about, if I enter values x and y, will the result be z? instead of, if I enter x and y, will the method call class A first, then call class B and then return the result of class A plus the result of class B?'. Testing lots of small units that integrate to form a complex program reduces the amount of uncertain variables compared to a large monolithic end-to-end tests. Unit tests are used in most of the companies production classes to ensure good coverage of the entire codebase. Within the company, the Java unit testing framework JUnit is used.

JUnit5 test for checking in process in FlightBooking.java,

```
public boolean checkIn(){
    if(LocalDateTime.now().isAfter(flight.getFlightStart())){
        hasMissedFlight = true;
        return false;
    }
    hasCheckedIn = true;
    checkInTime = LocalDateTime.now();
    return true;
}
```

The unit test created to test the checkIn method in the FlightBooking class.

```
1 import org.junit.jupiter.api.DisplayName;
2 import org.junit.jupiter.api.Test;
3 import org.mockito.Mockito;
4
5 import java.time.LocalDateTime;
6
  import static org.junit.jupiter.api.Assertions.assertFalse;
7
8 import static org.junit.jupiter.api.Assertions.assertTrue;
9
10 class FlightBookingTest {
       private Flight testFlight;
11
12
       private FlightBooking testFlightBooking;
13
```

```
14
15
       @Test
       @DisplayName("Check-in process with an on-time flight booking")
16
        public void checkIn() {
17
18
            LocalDateTime earlyDateTime = LocalDateTime.now().plusYears(1);
19
20
             Create a mocked class of testFlight testFlight could use
21
             an API for plane tracking, so creating a stub ensures that
22
            the test is independent
23
24
            testFlight = Mockito.mock(Flight.class);
25
            // Set what to return when getFlightStart() is called
            Mockito.when(testFlight.getFlightStart()).thenReturn(
26
                earlyDateTime
27
28
            );
29
            // Call the check-in process
31
            testFlightBooking = new FlightBooking(
32
                testFlight, "economy", 12, 200
            );
            assertTrue(testFlightBooking.checkIn());
34
       }
37
       @Test
       @DisplayName("Check-in process with a late flight booking")
38
       public void checkInLate() {
40
            LocalDateTime lateDateTime = LocalDateTime.now().minusYears(1);
41
            // Create another mocked class
42
43
            testFlight = Mockito.mock(Flight.class);
44
            // Set return time to the future to fail check-in
45
            Mockito.when(testFlight.getFlightStart()).thenReturn(
46
                lateDateTime
47
            );
48
49
            // Call the check-in process
            testFlightBooking = new FlightBooking(
51
                testFlight, "economy", 12, 200
52
            );
53
            assertFalse(testFlightBooking.checkIn());
54
       }
55
   }
```

Integration tests

Integration, or service layer, testing involves verifying that independent components of the program successfully interact and connect together as expected (Contan et al., 2018). These independent components include be databases, files, APIs, user inputs, and so on. These tests are one level above

the isolation of unit tests, but below end-to-end testing. Integration testing is split into 2 areas, narrow and broad integration testing. The former tests: exercise the code that interacts with the separate component, use test doubles - not production or development services in the test, and number in higher numbers than the latter (Fowler, 2018a). Whereas, broad testing requires live versions of every service, testing all code paths; not just those that interact with separate services. Therefore, narrow integration tests will run quicker and provide earlier feedback at the expense of the test's depth and code coverage. Thus, it is important to use both tests; a sizeable amount of narrow tests regularly running will spot most integration errors. Then, the broad tests can be run less frequently, such as during deployment pipelines, to spot any errors that passed through the narrow tests.

Narrow integration tests are implemented through many libraries like: JUnit, Spring, and testcontainers. Valley Cruises' service requires an SQL database for customer information. This external service needs integration testing with the Customer class and code that reads the database. Using the library testcontainers, temporary isolated SQL database through docker, we then connect to it, interact with the database through the customer's SQL classes, and check if those interactions propagate to the database. If the tests succeed, the database and program are successfully integrated. In Valley Cruises application, narrow integration tests will be used with the service's database for customer, holiday, flight, and cruise information. Furthermore, narrow integration tests can be used for any file input or outputs; these could be reading images, Welsh language localisation text, or configuration files for the service.

Integration test using testcontainer and the Customer class (testcontainers, [no date]),

```
1 import org.junit.jupiter.api.Test;
2 import org.junit.jupiter.api.AfterAll;
3 import org.junit.jupiter.api.BeforeAll;
4 import org.junit.jupiter.api.BeforeEach;
5 import org.junit.jupiter.api.DisplayName;
6 import org.testcontainers.containers.PostgreSQLContainer;
7
8 import static org.junit.jupiter.api.Assertions.assertEquals;
9
10
11
    * Test the program's integration with a database
12
13
14 public class CustomerIntegrationTest {
15
16
       /*
        Create a temporary database container to test a database's
17
18
        integration with the program
19
20
       static PostgreSQLContainer<?> postgres =
21
           new PostgreSQLContainer<>("postgres:16-alpine");
23
       Customer customer;
```

```
24
       // CustomerDatabase customerDatabase;
25
26
        /**
27
        * Start the database
28
        */
29
       @BeforeAll
        public static void startContainer() {
31
            postgres.start();
32
33
34
       /**
        * Stop the database container
       @AfterAll
37
        public static void stopContainer() {
38
39
            postgres.stop();
40
       }
41
42
        * Connect to the database and proceed to clean it of previous
43
44
        * entries
45
        */
46
       @BeforeEach
       public void setUpCleanDb() {
47
48
            customerDatabase = new CustomerDatabase(postgres.getJbdcUrl());
49
            customerDatabase.deleteAll();
50
       }
51
52
        /**
53
        * Test that {@code customerDatabase} integrates with and adds
54
        * the customer to the database
55
        */
56
       @Test
       @DisplayName("Database create customer")
57
        public void dbCreateCustomer() {
            customer = new Customer("Jake Real", "jakeemail@email.com",
59
                "3 Cool Road, Swandiff"
60
61
            );
            // Add the created customer to the database
62
            customerDatabase.addCustomer(customer)
63
            // Test that customer was created in the database
64
            assertEquals("Jake Real", customerDatabase.getCustomerByName(
                "Jake Real").getFullName()
66
67
            );
       }
68
69
70
        /**
71
        * Test that {@code customerDatabase} integrates with and deletes
72
         * the customer from the database
        */
74
       @Test
```

```
75
       @DisplayName("Database delete customer")
76
       public void dbDeleteCustomer() {
           customer = new Customer("Jake Real", "jakeemail@email.com",
                "3 Cool Road, Swandiff"
78
79
           );
           // Add the created customer to the database
81
           customerDatabase.addCustomer(customer);
           // Test that customer was created in the database
82
           assertEquals("Jake Real", customerDatabase.getCustomerByName(
83
               "Jake Real").getFullName()
84
85
           );
86
           // Delete the customer from the database
           customerDatabase.deleteCustomerById(customer.getId);
87
           // Check that there are no customers
89
           assertEquals(0, customerDatabase.getAllCustomers().size());
       }
90
91
92
   }
```

In a broad integration test, the process of creating a customer and booking the customer on a holiday and integration between these two concepts is tested. In addition, APIs that are external to Valley Cruise's network such as flight tracking APIs are undergo broad testing due to a lack of control over them.

Contract Testing

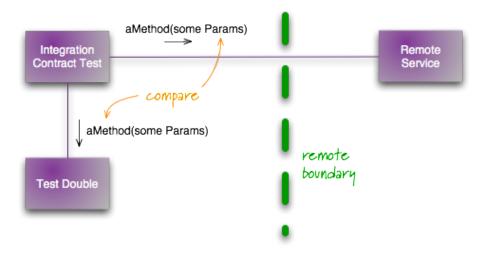

Figure 3: Contract testing (Fowler, 2011)

Integration testing is very effective when the tester controls the external services. However, speed and reliability decreases when tests occur between internal and external, remote services. The external

service can be slow, update with breaking changes, or have downtime. These are very undesirable in a test. To solve this issue, a test double is created through stubbing the remote service; this is when the class is emulated by the test software, returning predefined information when called. However, it is important that the test double is accurate to the remote service otherwise the company will not be aware when changes must be made to reflect the service's changes. Therefore, contract test's are used. Martin Fowler (2011) describes them as tests that, 'check all the calls against your test doubles return the same results as a call to the external service world'. Failures in the contact tests alert the developers to check the codebase and external service to verify they still integrate well. The test double are then updated accordingly. Within the Valley Cruises service, contract tests are used when interacting with plane tracking APIs, postcode APIs for customer registration, civil aviation authorities for pilot licencing.

End-to-end Testing

End-to-end tests cover the entire application. The frontend user interface of the application is automatically run through by the testing application. Inputs should correctly trigger their actions, the correct data should be displayed, and the UI states should change when expected to (Fowler, 2013). Furthermore, the layout of the frontend can be visually tested. As the testing tool proceeds through the service, screenshots of the layouts are taken; these screenshots are compared to previous iterations and set control screenshots. Any discrepancies are flagged to the developers for manual checking (Vaidya, 2023). End-end-testing's major advantage is that it exercises the whole application and its connections, discovering errors in components that other tests were unable to find. However, end-to-end tests are far more brittle than other tests. Browser peculiarities, timings, modal dialogues, and animations can create false positives that have to be debugged. Thus, these tests take more time and specialists to develop. Moreover, they must be regularly maintained when changes are made to user interface and data. Finally, these tests are far more expensive computationally, taking longer to complete. Therefore, far fewer of these tests are created and run, in accordance with the testing pyramid, so high-value scenarios are prioritised. In Valley Cruises' case, browsing the holidays, creating an account, adding the holiday to the cart, paying for the holiday, and managing holidays in your account would areas that use end-to-end tests.

End-to-end testing for this project is implemented by a framework supported in Java - Selenium. Selenium uses the browser to automatically call a website, interact and enter data into it, and then check that the correct changes are made. Whilst doing this, Selenium can take screenshots of the process, run in a headless, non-graphical browser, or run on a server with no graphical user interface.

Example of using Selenium to test logging in to Valley Cruises,

```
import io.github.bonigarcia.wdm.WebDriverManager;
import org.junit.jupiter.api.Test;
```

```
3 import org.junit.jupiter.api.AfterAll;
4 import org.junit.jupiter.api.BeforeAll;
5 import org.junit.jupiter.api.BeforeEach;
6 import org.junit.jupiter.api.DisplayName;
7 import org.openqa.selenium.By;
8 import org.openqa.selenium.WebDriver;
9 import org.openqa.selenium.firefox.FirefoxDriver;
10
import static org.junit.jupiter.api.Assertions.assertEquals;
12
13 public class LoginTest {
14
       private WebDriver driver;
15
       private String username = "testing";
       private String password = "testing";
16
17
18
       @BeforeAll
19
       public static void setUpDriver() throws Exception {
20
           WebDriverManager.firefoxdriver.setup();
21
22
23
       @BeforeEach
24
       public void setUp() {
25
           driver = new FirefoxDriver();
27
       @AfterEach
28
29
       public void tearDown() {
           driver.quit();
       }
32
33
       @Test
34
       public void loginWebsite() {
           driver.get("https://www.valleycruises.com/login");
           WebElement usernameField = driver.findElement(
               By.id("login-username")
38
           );
40
           WebElement passwordField = driver.findElement(
41
               By.id("login-password")
42
43
           WebElement loginButton = driver.findElement(
44
               By.id("login-button")
45
           );
46
           usernameField.sendKeys(username);
47
           passwordField.sendKeys(password);
48
49
           loginButton.click();
50
51
           WebElement usernameLabel = driver.findElement(
               By.id("label-username")
53
```

```
assertEquals(usernameField.getText(), username);
}

55  }
56 }
```

Manual Testing

Manual testing is when testers go through the program, using its features and checking for correct behaviour. The testers follow a test plan that describes the scope, methodology, schedule, needed resources and tools that are allocated for the test; this plan forms the general structure of the test. The tester then follows multiple more detailed test cases. These outline the: steps taken by the tester, the expected outcomes of said tests, and after testing, the actual outcomes of the test and whether it passed or failed. Various test cases can be seen in tables 1 and 2. Manual testing is most suitable for testing areas where automation and computers fail. These are: accessibility testing, computers are unable emulate how a visually impaired people will screen readers to access a service; layout testing, computers struggle to find visual defects in programs so manually testing on different layouts and screens is preferred; and exploratory testing, which emphasises tester freedom resulting in tests that cover areas that automation might miss. The company aims for a split of 75% automated testing with 25% manual testing, striking a balance between speed and cost.

Table 1: Tests for password input in frontend,

Test			Expected	Actual
number	Test data	Reason	outcome	outcome
1	Password = testing123@@	Test that a password meeting the requirements of containing more 7 characters or more, 2 or more numbers and symbols is accepted	Valid password	Valid password
2	Password = testing123	Test that a password not meeting the requirements of containing more 7 characters or more, 2 or more numbers and symbols is not accepted	Invalid password	Invalid password
3	Password = testing@@#	Test that a password not meeting the requirements of containing more 7 characters or more, 2 or more numbers and symbols is not accepted	Invalid password	Invalid password

Test number	Test data	Reason	Expected outcome	Actual outcome
4	Password = testing	Test that a password not meeting the requirements of containing more 7 characters or more, 2 or more numbers and symbols is not accepted	Invalid password	Invalid password

Table 2: Tests for searching by price in frontend,

Test number	Test data	Reason	Expected outcome	Actual outcome
1	Search = £2000	Test that a valid search amount correctly returns a search query	Valid search	Valid search
2	Search = -£2000	Test that a negative money search amounts does not return a search query as negative money is not possible	Invalid search	Invalid search

Static Testing

Finally, static testing is a subset of manual testing in which the program is not executed. Static tests involve checking that the program is fault tolerant. Code is checked for preconditions. These alter control flow to ensure potentially errenous values are not passed to problematic statements. For exmaple, using an **if** statement to prevent passing 0 as a divisor, or preventing negative numbers from being the radicand in a root.

Conclusion

In conclusion, the company uses a mixed testing strategy of automated and manual tests with a bias to automation. The structure of the automated tests follows the testing pyramid, with many unit tests, a medium number of integration and contract tests, and finally a fewer amount of end-to-end tests. This strategy results in a bottom-up approach to automated testing where most errors should be caught before the final end-to-end testing, ensuring that they are caught quickly before causing costing considerable resources to fix. The manual testing process covers areas that are difficult or too in depth to be automated, such as layout testing, accessibility testing, and freely exploring through the

program. Overall, the testing strategy of the company attempts to ensure fast development, whilst keeping good testing coverage of the released program in an attempt to catch errors prior to public release.
